

Isolated Fixed-Ratio DC-DC Converter

Features & Benefits

- Up to 150A continuous secondary current
- Up to 2206W/in³ power density
- 97.6% peak efficiency
- 2,250V_{DC} isolation
- Parallel operation for multi-kW arrays
- OV, OC, UV, short circuit and thermal protection
- 6123 through-hole ChiP package
 - 2.402" x 0.990" x 0.284"
(61.00mm x 25.14mm x 7.21mm)
- PMBus[™] management interface*

Typical Applications

- High End Computing Systems
- Automated Test Equipment
- Industrial Systems
- High Density Power Supplies
- Communications Systems
- Transportation

Product Ratings	
$V_{PRI} = 54V (36 - 60V)$	$I_{SEC} = \text{up to } 150A$
$V_{SEC} = 9V (6 - 10V)$ (NO LOAD)	$K = 1/6$

Product Description

The BCM6123x60E10A5yzz Bus Converter (BCM[®]) is a high efficiency Sine Amplitude Converter[™] (SAC[™]), operating from a 36 to 60V_{DC} primary bus to deliver an isolated, ratiometric secondary voltage from 6 to 10V_{DC}.

The BCM6123x60E10A5yzz offers low noise, fast transient response, and industry leading efficiency and power density. In addition, it provides an AC impedance beyond the bandwidth of most downstream regulators, allowing input capacitance normally located at the input of a PoL regulator to be located at the primary side of the BCM module. With a primary to secondary K factor of 1/6, that capacitance value can be reduced by a factor of 36x, resulting in savings of board area, material and total system cost.

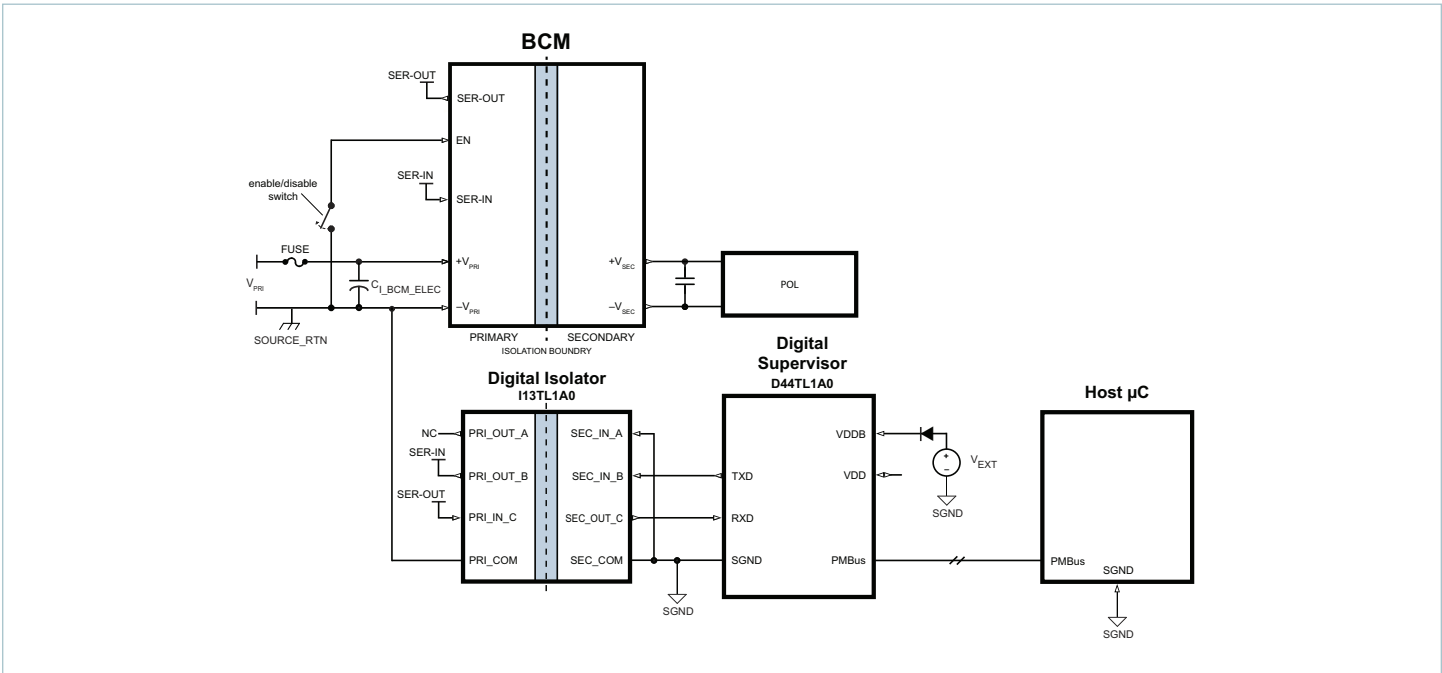

Leveraging the thermal and density benefits of Vicor's ChiP packaging technology, the BCM module offers flexible thermal management options with very low top and bottom side thermal impedances. Thermally-adept ChiP-based power components, enable customers to achieve low cost power system solutions with previously unattainable system size, weight and efficiency attributes, quickly and predictably.

*When used with D44TL1A0 and I13TL1A0 chipset

Typical Application

BCM6123x60E10A5y00 at Point of load

BCM6123x60E10A5y01 at Point of load

Pin Configuration

Pin Descriptions

Power Pins			
Pin Number	Signal Name	Type	Function
I1, J1, K1, L1	+V _{PRI}	PRIMARY POWER	Positive primary transformer power terminal
L'2	-V _{PRI}	PRIMARY POWER RETURN	Negative primary transformer power terminal
A1, D1, E1, H1, A'2, D'2, E'2, H'2	+V _{SEC}	SECONDARY POWER	Positive secondary transformer power terminal
B1, C1, F1, G1 B'2, C'2, F'2, G'2	-V _{SEC} *	SECONDARY POWER RETURN	Negative secondary transformer power terminal
Analog Control Signal Pins			
Pin Number	Signal Name	Type	Function
I'2	TM	OUTPUT	Temperature Monitor; primary side referenced signals
J'2	EN	INPUT	Enables and disables power supply; primary side referenced signals
K'2	VAUX	OUTPUT	Auxiliary Voltage Source; primary side referenced signals
PMBus Control Signal Pins			
Pin Number	Signal Name	Type	Function
I'2	SER-OUT	OUTPUT	UART transmit pin; Primary side referenced signals
J'2	EN	INPUT	Enables and disables power supply; Primary side referenced signals
K'2	SER-IN	INPUT	UART receive pin; Primary side referenced signals

*For proper operation an external low impedance connection must be made between listed -V_{SEC}1 and -V_{SEC}2 terminals.

PMBus™ System Diagram

The PMBus communication enabled bus converter provides accurate telemetry monitoring and reporting, threshold and warning limits adjustment, in addition to corresponding status flags.

The BCM internal μ C is referenced to primary ground. The Digital Isolator allows UART communication interface with the host Digital Supervisor at typical speed of 750kHz across the isolation barrier. One of the advantages of the Digital Isolator is its low power consumption. Each transmission channel is able to draw its internal bias circuitry directly from the input signal being transmitted to the output with minimal to no signal distortion.

The Digital Supervisor provides the host system μ C with access to an array of up to four BCMs. This array is constantly polled for status by the Digital Supervisor. Direct communication to individual BCM is enabled by a page command. For example, the page (0x00) prior to a telemetry inquiry points to the Digital Supervisor data and pages (0x01 – 0x04) prior to a telemetry inquiry points to the array of BCMs connected data. The Digital Supervisor constantly polls the BCM data through the UART interface.

The Digital Supervisor enables the PMBus compatible host interface with an operating bus speed of up to 400kHz. The Digital Supervisor follows the PMBus command structure and specification.

Please refer to the Digital Supervisor data sheet for more details.

Sine Amplitude Converter™ Point of Load Conversion

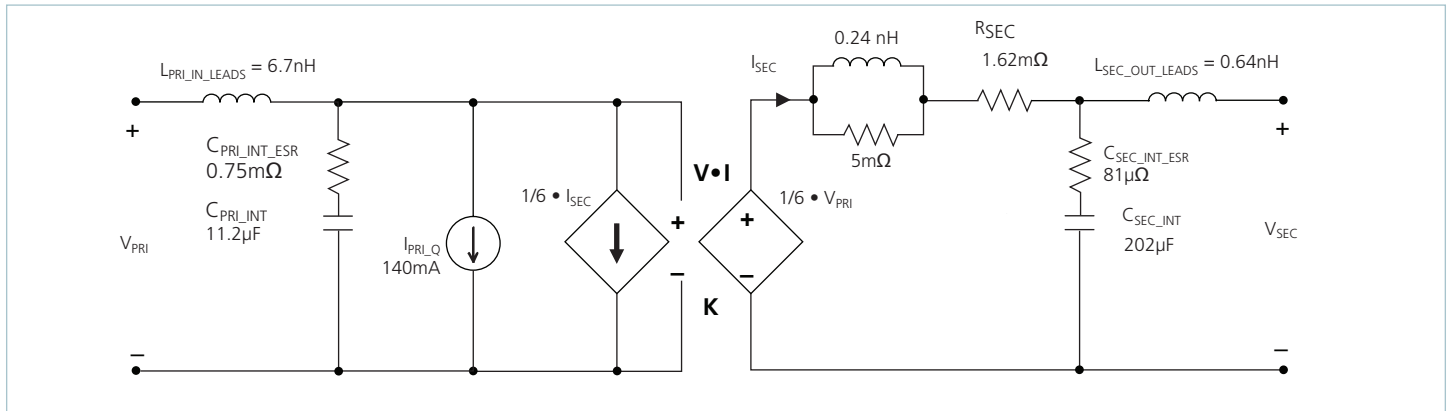

Figure 19 — BCM module AC model

The Sine Amplitude Converter (SAC™) uses a high frequency resonant tank to move energy from Primary to secondary and vice versa. The resonant LC tank, operated at high frequency, is amplitude modulated as a function of primary voltage and secondary current. A small amount of capacitance embedded in the primary and secondary stages of the module is sufficient for full functionality and is key to achieving high power density.

The BCM6123x60E10A5yzz SAC can be simplified into the preceding model.

At no load:

$$V_{SEC} = V_{PRI} \cdot K \tag{1}$$

K represents the “turns ratio” of the SAC.

Rearranging Eq (1):

$$K = \frac{V_{SEC}}{V_{PRI}} \tag{2}$$

In the presence of load, V_{SEC} is represented by:

$$V_{SEC} = V_{PRI} \cdot K - I_{SEC} \cdot R_{SEC} \tag{3}$$

and I_{SEC} is represented by:

$$I_{SEC} = \frac{I_{PRI} - I_{PRI_Q}}{K} \tag{4}$$

R_{SEC} represents the impedance of the SAC, and is a function of the R_{DSON} of the primary and secondary MOSFETs and the winding resistance of the power transformer. I_{PRI_Q} represents the quiescent current of the SAC control, gate drive circuitry, and core losses.

The use of DC voltage transformation provides additional interesting attributes. Assuming that $R_{SEC} = 0\Omega$ and $I_{PRI_Q} = 0A$, Eq. (3) now becomes Eq. (1) and is essentially load independent, resistor R is now placed in series with V_{PRI} .

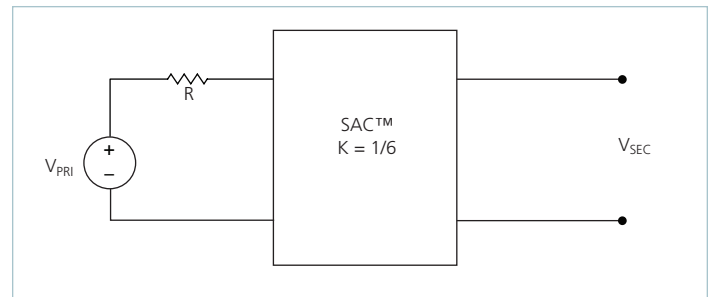

Figure 20 — K = 1/6 Sine Amplitude Converter with series primary resistor

The relationship between V_{PRI} and V_{SEC} becomes:

$$V_{SEC} = (V_{PRI} - I_{PRI} \cdot R) \cdot K \tag{5}$$

Substituting the simplified version of Eq. (4) (I_{PRI_Q} is assumed = 0A) into Eq. (5) yields:

$$V_{SEC} = V_{PRI} \cdot K - I_{SEC} \cdot R \cdot K^2 \tag{6}$$

This is similar in form to Eq. (3), where R_{SEC} is used to represent the characteristic impedance of the SAC™. However, in this case a real R on the primary side of the SAC is effectively scaled by K^2 with respect to the secondary.

Assuming that $R = 1\Omega$, the effective R as seen from the secondary side is $28m\Omega$, with $K = 1/6$.

A similar exercise should be performed with the addition of a capacitor or shunt impedance at the primary of the SAC. A switch in series with V_{PRI} is added to the circuit. This is depicted in Figure 21.

Figure 21 — Sine Amplitude Converter with primary capacitor

A change in V_{PRI} with the switch closed would result in a change in capacitor current according to the following equation:

$$I_C(t) = C \frac{dV_{PRI}}{dt} \quad (7)$$

Assume that with the capacitor charged to V_{PRI} , the switch is opened and the capacitor is discharged through the idealized SAC. In this case,

$$I_C = I_{SEC} \cdot K \quad (8)$$

substituting Eq. (1) and (8) into Eq. (7) reveals:

$$I_{SEC} = \frac{C}{K^2} \cdot \frac{dV_{SEC}}{dt} \quad (9)$$

The equation in terms of the secondary has yielded a K^2 scaling factor for C, specified in the denominator of the equation.

A K factor less than unity results in an effectively larger capacitance on the secondary when expressed in terms of the primary. With a $K = 1/6$ as shown in Figure 21, $C = 1\mu F$ would appear as $C = 36\mu F$ when viewed from the secondary.

Low impedance is a key requirement for powering a high-current, low-voltage load efficiently. A switching regulation stage should have minimal impedance while simultaneously providing appropriate filtering for any switched current. The use of a SAC between the regulation stage and the point of load provides a dual benefit of scaling down series impedance leading back to the source and scaling up shunt capacitance or energy storage as a function of its K factor squared. However, the benefits are not useful if the series impedance of the SAC is too high. The impedance of the SAC must be low, i.e. well beyond the crossover frequency of the system.

A solution for keeping the impedance of the SAC low involves switching at a high frequency. This enables small magnetic components because magnetizing currents remain low. Small magnetics mean small path lengths for turns. Use of low loss core material at high frequencies also reduces core losses.

The two main terms of power loss in the BCM module are:

- No load power dissipation (P_{PRI_NL}): defined as the power used to power up the module with an enabled powertrain at no load.
- Resistive loss (P_{RSEC}): refers to the power loss across the BCM module modeled as pure resistive impedance.

$$P_{DISSIPATED} = P_{PRI_NL} + P_{RSEC} \quad (10)$$

Therefore,

$$P_{SEC_OUT} = P_{PRI_IN} - P_{DISSIPATED} = P_{PRI_IN} - P_{PRI_NL} - P_{RSEC} \quad (11)$$

The above relations can be combined to calculate the overall module efficiency:

$$\eta = \frac{P_{SEC_OUT}}{P_{PRI_IN}} = \frac{P_{PRI_IN} - P_{PRI_NL} - P_{RSEC}}{P_{PRI_IN}} \quad (12)$$

$$= \frac{V_{PRI} \cdot I_{PRI} - P_{PRI_NL} - (I_{SEC})^2 \cdot R_{SEC}}{V_{PRI} \cdot I_{PRI}}$$

$$= 1 - \left(\frac{P_{PRI_NL} + (I_{SEC})^2 \cdot R_{SEC}}{V_{PRI} \cdot I_{PRI}} \right)$$

Input and Output Filter Design

A major advantage of SAC™ systems versus conventional PWM converters is that the transformer based SAC does not require external filtering to function properly. The resonant LC tank, operated at extreme high frequency, is amplitude modulated as a function of primary voltage and secondary current and efficiently transfers charge through the isolation transformer. A small amount of capacitance embedded in the primary and secondary stages of the module is sufficient for full functionality and is key to achieving power density.

This paradigm shift requires system design to carefully evaluate external filters in order to:

- Guarantee low source impedance:

To take full advantage of the BCM module’s dynamic response, the impedance presented to its primary terminals must be low from DC to approximately 5MHz. The connection of the bus converter module to its power source should be implemented with minimal distribution inductance. If the interconnect inductance exceeds 100nH, the primary should be bypassed with a RC damper to retain low source impedance and stable operation. With an interconnect inductance of 200nH, the RC damper may be as high as 1µF in series with 0.3Ω. A single electrolytic or equivalent low-Q capacitor may be used in place of the series RC bypass.

- Further reduce primary and/or secondary voltage ripple without sacrificing dynamic response:

Given the wide bandwidth of the module, the source response is generally the limiting factor in the overall system response. Anomalies in the response of the primary source will appear at the secondary of the module multiplied by its K factor.

- Protect the module from overvoltage transients imposed by the system that would exceed maximum ratings and induce stresses:

The module primary/secondary voltage ranges shall not be exceeded. An internal overvoltage lockout function prevents operation outside of the normal operating primary range. Even when disabled, the powertrain is exposed to the applied voltage and power MOSFETs must withstand it.

Total load capacitance at the secondary of the BCM module shall not exceed the specified maximum. Owing to the wide bandwidth and low secondary impedance of the module, low-frequency bypass capacitance and significant energy storage may be more densely and efficiently provided by adding capacitance at the primary of the module. At frequencies <500kHz the module appears as an impedance of R_{SEC} between the source and load.

Within this frequency range, capacitance at the primary appears as effective capacitance on the secondary per the relationship defined in Eq. (13).

$$C_{SEC_EXT} = \frac{C_{PRI_EXT}}{K^2} \tag{13}$$

This enables a reduction in the size and number of capacitors used in a typical system.

Thermal Considerations

The ChiP package provides a high degree of flexibility in that it presents three pathways to remove heat from internal power dissipating components. Heat may be removed from the top surface, the bottom surface and the leads. The extent to which these three surfaces are cooled is a key component for determining the maximum current that is available from a ChiP, as can be seen from Figure 1.

Since the ChiP has a maximum internal temperature rating, it is necessary to estimate this internal temperature based on a real thermal solution. Given that there are three pathways to remove heat from the ChiP, it is helpful to simplify the thermal solution into a roughly equivalent circuit where power dissipation is modeled as a current source, isothermal surface temperatures are represented as voltage sources and the thermal resistances are represented as resistors. Figure 22 shows the “thermal circuit” for a 6123 ChiP BCM module in an application where the top, bottom, and leads are cooled. In this case, the BCM power dissipation is PD_{TOTAL} and the three surface temperatures are represented as T_{CASE_TOP}, T_{CASE_BOTTOM}, and T_{LEADS}. This thermal system can now be very easily analyzed using a SPICE simulator with simple resistors, voltage sources, and a current source. The results of the simulation would provide an estimate of heat flow through the various pathways as well as internal temperature.

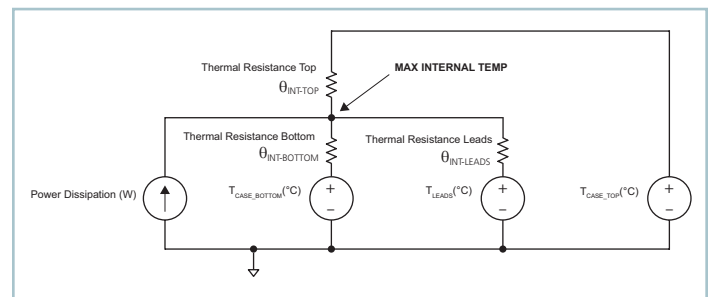

Figure 22 — Top case, bottom case and leads thermal model

Alternatively, equations can be written around this circuit and analyzed algebraically:

$$T_{INT} - PD_1 \cdot \theta_{INT-TOP} = T_{CASE_TOP}$$

$$T_{INT} - PD_2 \cdot \theta_{INT-BOTTOM} = T_{CASE_BOTTOM}$$

$$T_{INT} - PD_3 \cdot \theta_{INT-LEADS} = T_{LEADS}$$

$$PD_{TOTAL} = PD_1 + PD_2 + PD_3$$

Where T_{INT} represents the internal temperature and PD₁, PD₂, and PD₃ represent the heat flow through the top side, bottom side, and leads respectively.

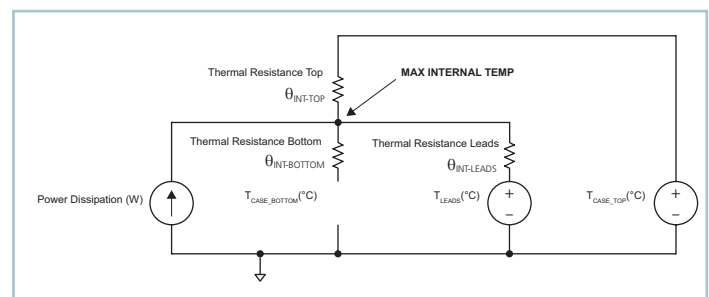

Figure 23 — Top case and leads thermal model

Figure 23 shows a scenario where there is no bottom side cooling. In this case, the heat flow path to the bottom is left open and the equations now simplify to:

$$T_{INT} - PD_1 \cdot \theta_{INT-TOP} = T_{CASE_TOP}$$

$$T_{INT} - PD_3 \cdot \theta_{INT-LEADS} = T_{LEADS}$$

$$PD_{TOTAL} = PD_1 + PD_3$$

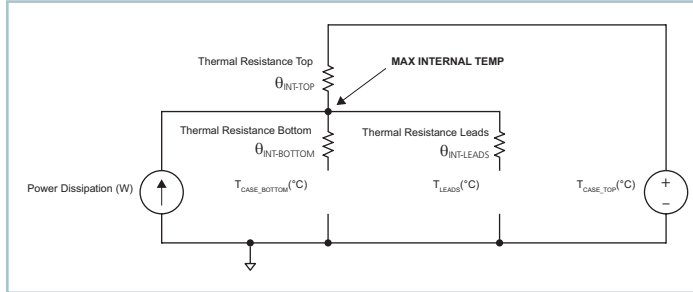

Figure 24 — Top case thermal model

Figure 24 shows a scenario where there is no bottom side and leads cooling. In this case, the heat flow paths to the bottom and leads are left open and the equations now simplify to:

$$T_{INT} - PD_1 \cdot \theta_{INT-TOP} = T_{CASE_TOP}$$

$$PD_{TOTAL} = PD_1$$

Please note that Vicor has a suite of online tools, including a simulator and thermal estimator which greatly simplify the task of determining whether or not a BCM thermal configuration is valid for a given condition. These tools can be found at: <http://www.vicorpower.com/powerbench>.

Current Sharing

The performance of the SAC™ topology is based on efficient transfer of energy through a transformer without the need of closed loop control. For this reason, the transfer characteristic can be approximated by an ideal transformer with a positive temperature coefficient series resistance.

This type of characteristic is close to the impedance characteristic of a DC power distribution system both in dynamic (AC) behavior and for steady state (DC) operation.

When multiple BCM modules of a given part number are connected in an array they will inherently share the load current according to the equivalent impedance divider that the system implements from the power source to the point of load.

Some general recommendations to achieve matched array impedances include:

- Dedicate common copper planes within the PCB to deliver and return the current to the modules.
- Provide as symmetric a PCB layout as possible among modules
- An input filter is required for an array of BCMs in order to prevent circulating currents.

For further details see:

[AN:016 Using BCM Bus Converters in High Power Arrays.](#)

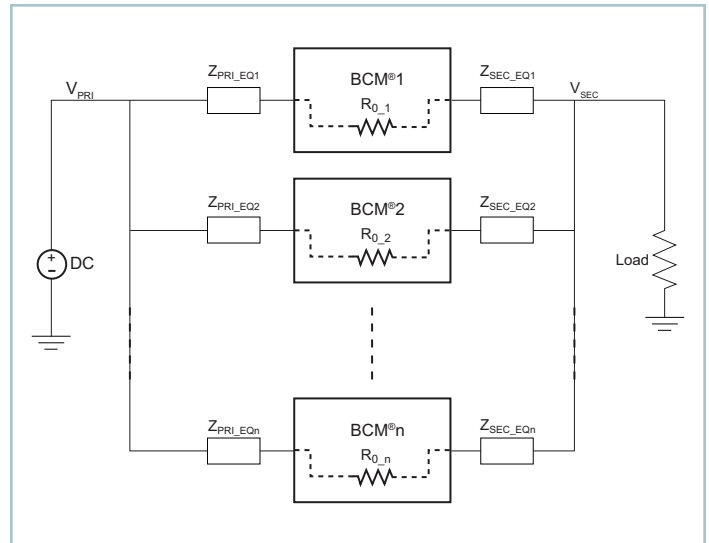

Figure 25 — BCM module array

Fuse Selection

In order to provide flexibility in configuring power systems ChiP modules are not internally fused. Input line fusing of ChiP products is recommended at system level to provide thermal protection in case of catastrophic failure.

The fuse shall be selected by closely matching system requirements with the following characteristics:

- Current rating (usually greater than maximum current of BCM module)
- Maximum voltage rating (usually greater than the maximum possible input voltage)
- Ambient temperature
- Nominal melting I²t
- Recommend fuse: ≤ 40A Littelfuse 456 Series (primary side)

Reverse Operation

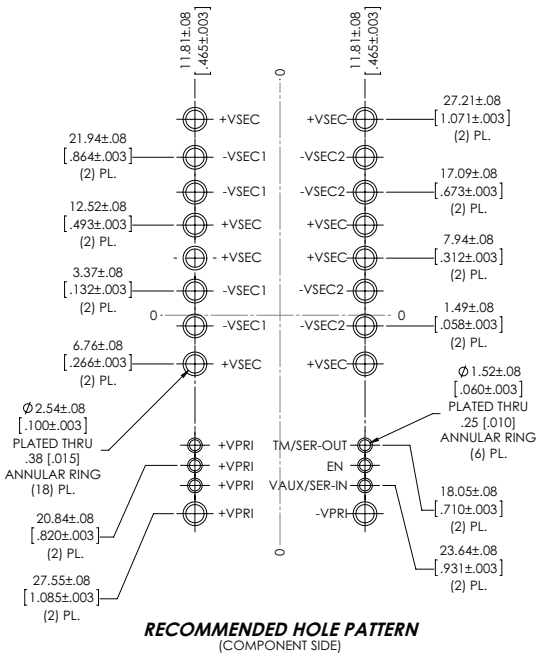

BCM modules are capable of reverse power operation. Once the unit is started, energy will be transferred from secondary back to the primary whenever the secondary voltage exceeds V_PRI • K. The module will continue operation in this fashion for as long as no faults occur.

Transient operation in reverse is expected in cases where there is significant energy storage on the secondary and transient voltages appear on the primary.
